

SKF composite plain bearings

Compact and maintenance-free

The SKF® brand now stands for more than ever before, and means more to you as a valued customer.

While SKF maintains its leadership as the hallmark of quality bearings throughout the world, new dimensions in technical advances, product support and services have evolved SKF into a truly solutions-oriented supplier, creating greater value for customers.

These solutions encompass ways to bring greater productivity to customers, not only with breakthrough application-specific products, but also through leading-edge design simulation tools and consultancy services, plant asset efficiency maintenance programmes, and the industry's most advanced supply management techniques.

The SKF brand still stands for the very best in rolling bearings, but it now stands for much more.

Compact and maintenance-free

A

Composite plain bearings are primarily used for bearing arrangements where heavy loads have to be supported and where rotational or oscillating movements are relatively slow. Because of their good sliding properties and compact design, these plain bearings are particularly suitable for bearing arrangements where

- maintenance-free operation is a prerequisite
- there is a risk of lubricant starvation
- lubricants can not be used or are forbidden
- space is limited.

Typical application examples for SKF composite plain bearings can be found on **pages 49 to 57**.

Characteristics

The important characteristics of SKF composite plain bearings include

- maintenance-free
- no lubrication required (PTFE composite)
- initial lubrication required (POM composite)
- minimum wall thickness, minimum space requirements
- accommodation of heavy loads
- wide range of operating temperatures
- good sliding properties
- virtually no stick-slip
- high wear-resistance
- less sensitive to edge loading (POM composite)
- no machining required.

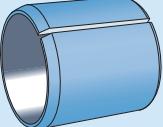

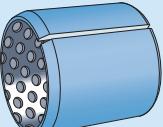

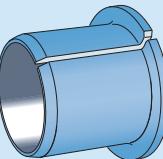

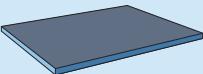

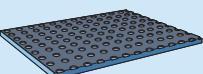

The assortment

The standard range of SKF composite plain bearings is very comprehensive and covers almost every standard size. The range is shown in the product overview in **table 1** and comprises

- straight bushings
- flanged bushings
- thrust washers
- strips.

Table 1

Bearing type	Series	Bore diameter range	Lubrication	Operating temperature range	
Straight bushings					
PTFE composite					
		PCM .. E	3–300 mm	None	–200 to +250 °C
		PCZ .. E	1/8–7 in	None	–200 to +250 °C
POM composite					
		PCM .. M	8–300 mm	Initial lubrication only	–40 to +110 °C short periods +130 °C
		PCZ .. M	3/8–4 in	Initial lubrication only	–40 to +110 °C short periods +130 °C

Series	Characteristics	Product table on page
PCM .. E	Metric straight bushings of triple-layer PTFE composite material, (→ page 6). Suitable for bearing arrangements that have to support radial loads only. For slow rotational or oscillating movements. Initial lubrication not required. Maintenance-free.	28
PCZ .. E	Inch straight bushings of triple-layer PTFE composite material, (→ page 6). Suitable for bearing arrangements that have to support radial loads only. For slow rotational or oscillating movements. Initial lubrication not required. Maintenance-free.	38
PCM .. M	Metric straight bushings of triple-layer POM composite material (→ page 6). Suitable for bearing arrangements that have to support radial loads only. For slow rotational or oscillating movements as well as linear movements. Initial lubrication required. Maintenance-free, except where there is a risk of misalignment, edge loading or moderate to severe contamination.	28
PCZ .. M	Inch straight bushings of triple-layer POM composite material (→ page 6). Suitable for bearing arrangements that have to support radial loads only. For slow rotational or oscillating movements as well as linear movements. Initial lubrication required. Maintenance-free, except where there is a risk of misalignment, edge loading or moderate to severe contamination.	38
PCM .. E	Metric flanged bushings, made of triple-layer PTFE composite material, (→ page 6). Suitable for bearing arrangements that have to accommodate radial loads and axial loads in one direction. For slow rotational and oscillating movements. Maintenance-free. No lubrication required.	42
PCM .. E	Metric thrust washers of triple-layer PTFE composite material, (→ page 6). Suitable for space-saving axial locating bearing arrangements. For slow rotational or oscillating movements. Initial lubrication not required. Maintenance-free.	43
PCM .. M	Metric thrust washers of triple-layer POM composite material (→ page 6). Suitable for space-saving axial locating bearing arrangements. For slow rotational or oscillating movements. Initial lubrication required. Maintenance-free except where there is a risk of edge loading or moderate to severe contamination.	43
PCMS .. E	Strips of triple-layer PTFE composite material, (→ page 6). The strips can be bent, pressed, cut etc. to fit the application. Suitable for space-saving arrangements of all types. Initial lubrication not required. Maintenance-free.	44
PCMS .. M	Strips of triple-layer POM composite material (→ page 6). The strips can be bent, pressed, cut etc. to fit the application. Suitable for space-saving plain bearing arrangements of all types and where there is a risk of moderate contamination or edge loading. Initial lubrication required.	44

Materials

There are two standard types of composite material for SKF plain bearings: PTFE composite and POM composite. Each is suitable for different applications.

PTFE composite

PTFE composite bearings consist of a sheet steel backing on which a 0,2 to 0,4 mm thick porous layer of tin/bronze is sintered (**→ fig. 1**). By a rolling process, the pores of the sintered layer are filled with a mixture of PTFE (polytetrafluoroethylene) and molybdenum disulphide (designation suffix E).

An additional 5 to 30 µm thick running-in layer of the mixture is then applied to the sintered tin/bronze. This additional layer provides an optimum combination of the mechanical properties of the sintered tin/bronze and the good sliding and lubricating properties of the PTFE mixture. PTFE composite bearings have good dimensional stability and thermal conductivity.

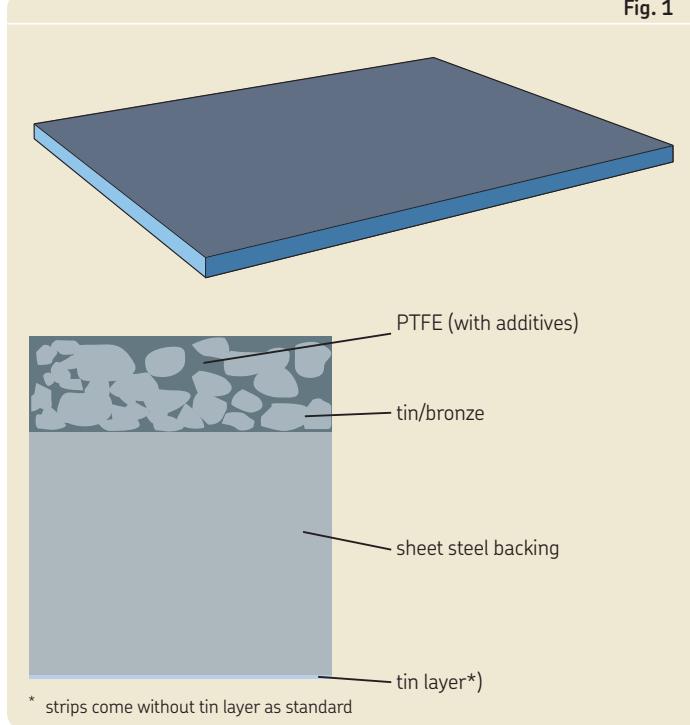

POM composite

Like PTFE composite bearings, POM composite bearings also have a sheet steel backing that is covered with a 0,2 to 0,4 mm thick layer of sintered tin/bronze (**→ fig. 2**). The principal characteristic of these bearings is their relatively thick (0,3 mm) layer of acetal resin (POM – polyoxymethylene) that is firmly attached to the sintered tin/bronze layer. The covering layer has pockets to retain grease.

The thickness of the covering layer makes these bearings less sensitive to misalignment and the edge loading associated with that misalignment.

PTFE composite material

Fig. 1

POM composite material

Fig. 2

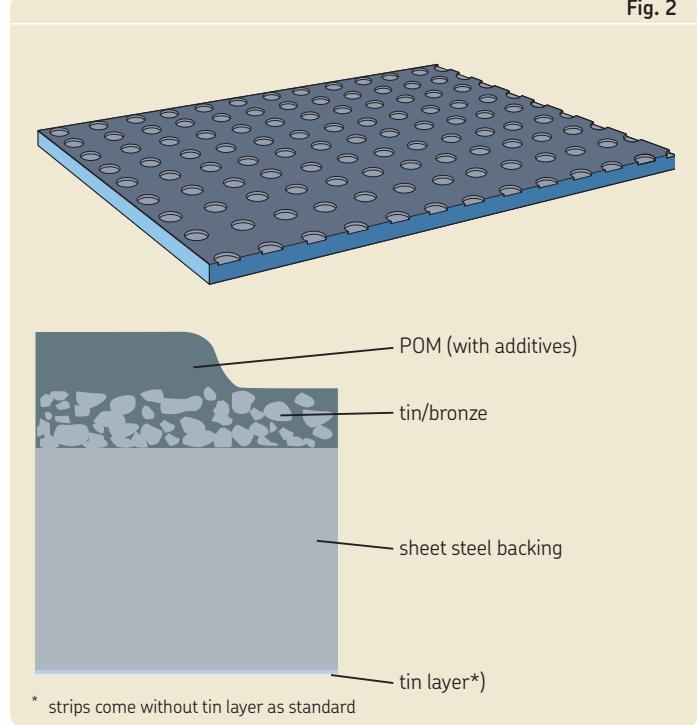

Table 2

A

Summary of characteristics of SKF PTFE composite and POM composite materials

Characteristics	PTFE composite	POM composite
Composition	Material variant E Steel backing with a layer of sintered tin/bronze; pores filled and covered with a layer (5 to 30 µm) of PTFE with molybdenum disulphide additives	Material variant M Steel backing with a layer of sintered tin/bronze; pores filled and covered with a layer (0,3 mm) of POM
Permissible specific static bearing load (N/mm ²)	250	250
Permissible specific dynamic bearing load (N/mm ²)	80	120
Maximum sliding velocity (m/s)	2	2,5
Operating temperature range (°C)	-200 to +250	-40 to +110 (+130 for short periods)
Coefficient of friction	0,03 to 0,25	0,02 to 0,20
Stick-slip effect	Negligible	Negligible
Wear layer thickness (mm)	0,2	0,3
Lubrication	Not required	Initial lubrication required
Ability to support edge loads (e.g. resulting from misalignment)	Fair	Good
Ability to carry alternating loads	Good	Fair
Ability to accommodate linear movements	Fair	Good
Machining of sliding surface after mounting	Calibration	Drilling, turning, (reaming)
Recommended housing tolerance for metric bushings	H7	H7
Recommended shaft tolerance for metric bushings	f7 (for d ≤ 75 mm) h8 (for d > 75 mm)	h8 (h7)
Required surface roughness of mating surface (µm)	R _z ≤ 3 R _a ≤ 0,4	R _z ≤ 6 R _a ≤ 0,8
Permissible surface machining of mating surface	Commercial shafts (ground or drawn)	Commercial shafts (drawn or fine turned)

Machinability of composite materials

With the exception of the sliding layer, SKF composite bushings can be machined using conventional methods.

If bushings are required to have a smaller width than the standard size, this can easily be achieved by turning. It is also possible to drill lubrication holes. However, any burrs must be removed, particularly from the sliding surface.

Strips can be bent, pressed, cut, or drilled to fit the individual application. When cutting or drilling, it is advisable to work from the sliding surface side to avoid creating burrs in the sliding layer.

Any metal surfaces that are exposed as a result of machining should be protected against corrosion.

Calibrating mandrel

d_k = diameter of the calibrating mandrel

B = bushing width

Minimum hardness: 50 HRC

Surface roughness: $R_z \approx 1 \mu\text{m}$

Machining the bore of PTFE composite bushings

PTFE composite bushings conform to ISO 3547:2006 and are ready for installation. Any re-sizing of the bore, i.e. the sliding surface, will reduce the service life of the bushings and should only be done in exceptional cases. If re-sizing is necessary, the bore should be calibrated, using a mandrel/resizing tool (→ fig. 3).

Because various criteria, like material and wall thickness of the housing as well as the deviation of cylindrical form, have to be taken into consideration, SKF recommends using a calibrated mandrel to re-size the bore. After resizing, bushing bore expansion tests and application field tests should be undertaken prior to the release of a final product. When machining the calibrating mandrel, the diameter d_k should be made in a first step about 60 to 80 μm larger than the maximum value listed in the column "Bore diameter of mounted bushing" in **table 1 on page 16**.

Guideline values for the requisite interference of the calibrating mandrel as a function of the desired widening of the bushing bore for various bushing bore diameters can be obtained from **diagram 1**. The diagram is based on tests with bushings of different sizes and valid for bushings mounted in a housing with an outside diameter $D_G = 2 \times$ bushing outside diameter D (→ fig. 3). If mandrel expansion tests show that the bore is too wide, the calibrating mandrel should be reground and the tests repeated on new bushings.

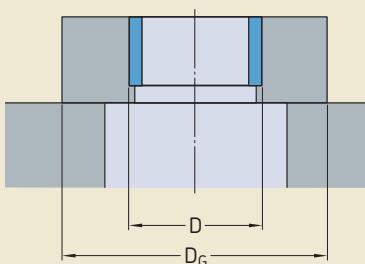

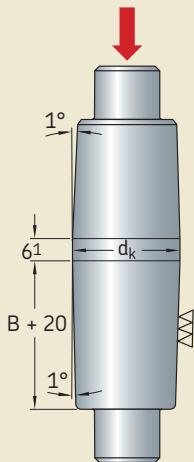

Machining the bore of POM composite bushings

Bushings made of POM composite material are ready for installation. However, if necessary, the bushing bore can be machined to size while mounted in its housing. After machining the bore, the sliding surface should have an R_a value of max 2,5 μm . The following machining recommendations will provide good results when a poly-crystalline diamond cutting tool is used

- cutting speed > 150 m/min
- slow feed rate (0,05 to 0,1 mm/revolution)
- cutting depth 0,1 mm.

To prevent excessive heat build-up of the acetal resin, and to remove the swarf produced during machining, a constant supply of compressed air (at a low pressure) should be applied to the bushing during any machining operation.

Fig. 3

Friction

Load, sliding velocity and operating temperature are primary factors in determining the friction in composite plain bearings. Friction is also influenced by the roughness of the surface on which the bearing runs, the degree of contamination and the lubrication conditions.

For PTFE composite bearings, the coefficient of friction μ lies between 0,03 and 0,25 depending on the operating conditions. Similar values are found for the POM composite material, but the presence or constant supply of lubricating fluids serves to decrease friction. The lowest values are normally obtained where there are high specific loads and low sliding velocities (\rightarrow guideline values for μ in **diagram 2**). Under particularly unfavourable operating conditions, like light loads, high velocities or inadequate surfaces, the maximum guideline values may be exceeded. The coefficient of friction for PTFE composite bearings increases at temperatures above +100 °C.

Stick-slip effects are negligible for PTFE and POM bearings.

Running-in

During a short running-in phase there will be some transfer of PTFE material from the covering layer to the counterface. After this transfer has taken place, the characteristic low friction and wear properties of these bearings will be obtained.

Chemical properties

The steel backing and the sintered tin/bronze layer are the primary factors in determining the chemical resistance of SKF composite plain bearings, as the sliding (covering) layers are resistant to most chemicals. The covering layer is virtually inert because of its PTFE content, although at elevated temperatures molten alkali metals and free fluorine will attack it. The acetal resin-covering layer of the POM composite bearing is largely resistant to organic substances.

At room temperature the sintered tin/bronze structure has good resistance to sea water, steam, atmospheric influences, salt solutions and sulphuric acid, but not to oxidizing acids or media containing ammonia.

All exposed surfaces of the steel backing are electrolytically tin-plated but this provides

only limited protection against corrosion in most applications. In cases where the bearings are to be exposed to corrosive media, or where there is a danger of corrosion in the contact between the steel backing and the housing material, the backing can be protected by a nickel, chromium or zinc coating applied electrolytically. Further details can be supplied on request.

Electrical properties

Bearings made from POM composite, because of their acetal resin-covering layer, may act as electrical insulators when new. To avoid the build-up of static electricity, components at risk should be grounded.

Requisite interference of the calibrating mandrel

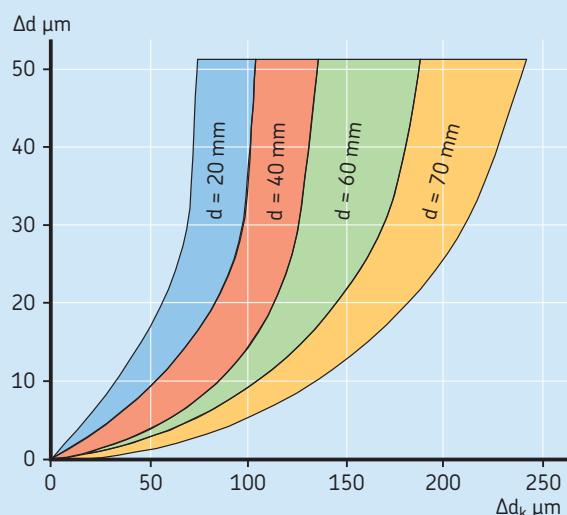

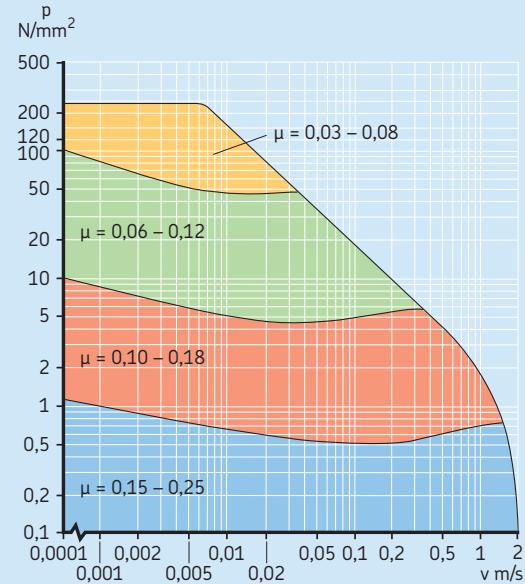

Diagram 1

Guideline values for the coefficient of friction μ of PTFE composite plain bearings

Selection of bearing size

The load carrying ability and wear characteristics of SKF composite plain bearings are governed by the specific conditions of a particular application. Therefore, any calculation can only provide approximate values. In order to determine the required size of a bearing, the load carrying capacity, the applied loads, the rating life requirements and operational reliability must all be considered. The load carrying capacity is expressed by the basic dynamic load rating C and the basic static load rating C_0 . Values of the load ratings can be found in the product tables.

Basic load ratings

Basic dynamic load ratings

The basic dynamic load rating C is used together with other influencing factors, to determine the basic rating life of a bearing. As a rule it represents the maximum load that a bearing can sustain at room temperature when the sliding contact surfaces are in motion. The maximum permissible load in any individual application should always be considered in relation to the desired rating life. The basic dynamic load ratings quoted in the product tables are based on the effective projected sliding surface and the specific load factor K that takes the different composite materials into consideration.

It is assumed in this definition that the load acting on a bushing or flanged bushing is purely radial and that the load acting on a thrust washer is purely axial and applied at the centre. Dynamic load conditions are essentially oscillating movements or rotations under load, but can include micro sliding under variable load (e.g. as a result of vibration) or operation under high frequency alternating loads. Where oscillating movements or rotation under load usually produce wear, the other conditions may result in fatigue.

Basic static load ratings

The basic static load rating C_0 is defined as the maximum load that an SKF composite bushing, flanged bushing or thrust washer can support when stationary at room temperature without permanently deforming the sliding layer and jeopardizing its performance. It is assumed that the bearing is adequately supported by the associated components of

the bearing arrangement. In order to fully exploit the static load rating of a bearing it is generally necessary to use shafts and housings made of high-strength materials. The basic static load rating must also be considered when bearings are dynamically loaded and are subjected to additional heavy shock loads. The total load in these cases must not exceed the basic static load rating.

pv operating ranges for PTFE composite plain bearings

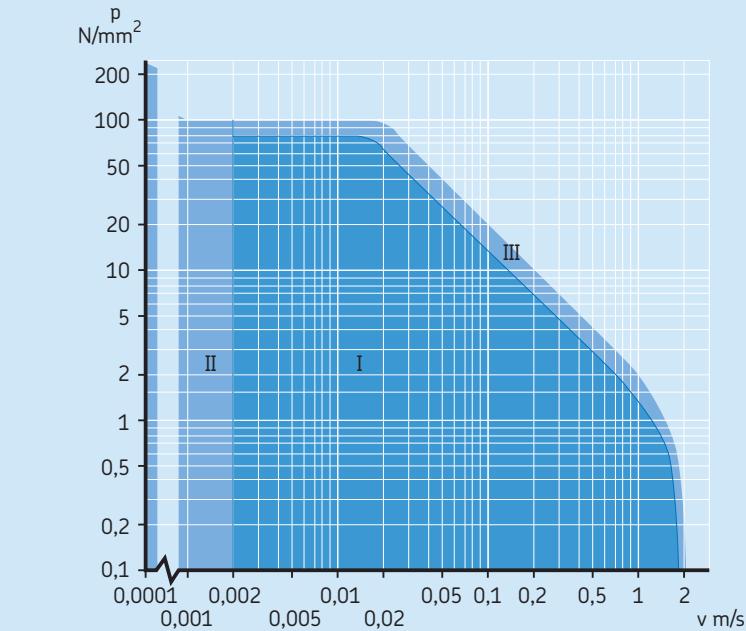

Diagram 1

pv operating ranges

I Basic rating life equation valid

II Quasi-static range; SKF should be consulted before the rating life equation is used

III Operation possible, e.g. if heat removal is very good; SKF should be consulted before the rating life equation is used

Basic rating life

The basic rating life of a composite plain bearing is expressed in number of oscillations or revolutions, or in operating hours. It represents the operating period under test conditions that is ended when one of the criteria for the end of the basic rating life is reached

- increase in operating clearance
- plastic deformation of the sliding layer
- fatigue.

A distinction is made between the basic rating life and the service life actually achieved.

The basic rating life is a guideline value that will be attained or exceeded by the majority of a large number of apparently identical bearings under the same test conditions.

The service life actually achieved by apparently identical bearings under identical operating conditions has been found to differ both in laboratory endurance tests and in service at operating conditions. These include not only the magnitude and type of load but also other factors such as contamination, corrosion, load and movement cycles of high frequency and shock loads. These factors are difficult or even impossible to quantify.

Requisite bearing size

The type and action mode of the load, the expected operating temperature, lubrication and maintenance requirements etc. all influence the choice of the bearing type and design.

To determine the requisite size of a composite plain bearing, start with the basic rating life for the application. The basic rating life will take the type of machine, the operating conditions, and operational reliability for that machine into consideration.

As a first approximation a guideline value of the load ratio $C/P = 2$ can be used to obtain the requisite basic dynamic load rating C . A suitable bearing can then be selected from the product tables.

pv operating range

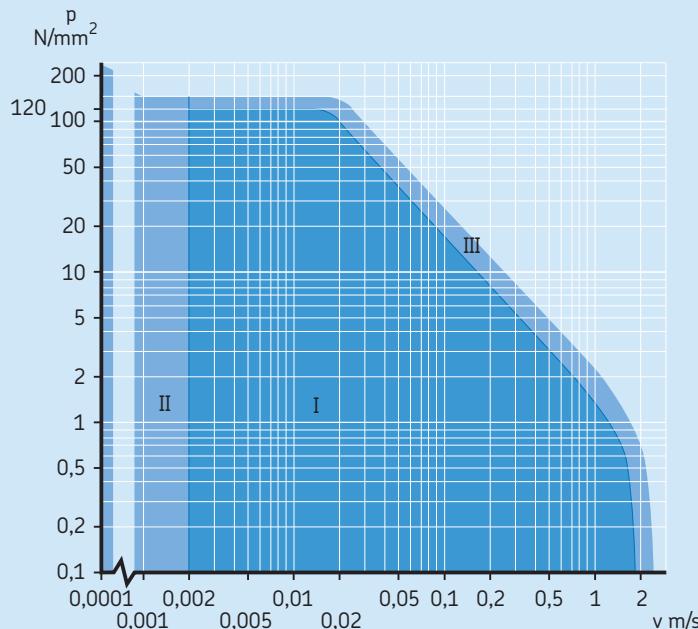

Check whether the chosen size can be used under the actual load and sliding velocity conditions using **diagram 1** for PTFE composite or **diagram 2** for POM composite. The data required – p (specific bearing load) and v (sliding velocity) – can be calculated using the equations provided on **page 12**.

If the operating data lie within range I of the pv diagram, the basic rating life of the bearing can be determined using the equation provided in the section “Calculating basic rating life” on **page 13**. If the data lie within the range II or III of the diagram, either contact the SKF application engineering service or test the application to see if the bearing can be used. Alternatively, a different bearing can be chosen so that the values for p and v fall within range I.

For flanged bushings check the suitability of the bushing and flange separately.

Diagram 2

pv operating ranges for POM composite plain bearings

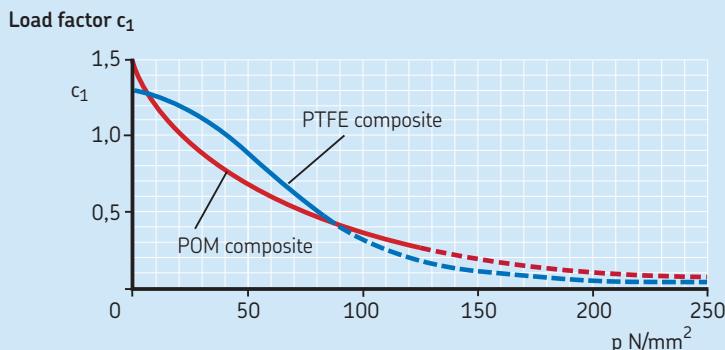

pv operating ranges

I Basic rating life equation valid

II Quasi-static range; SKF should be consulted before the rating life equation is used

III Operation possible, e.g. if heat removal is very good; SKF should be consulted before the rating life equation is used

Diagram 3

Determining specific bearing load

Specific bearing load can be determined from

$$p = K \frac{F}{C}$$

where

p = specific bearing load, N/mm²

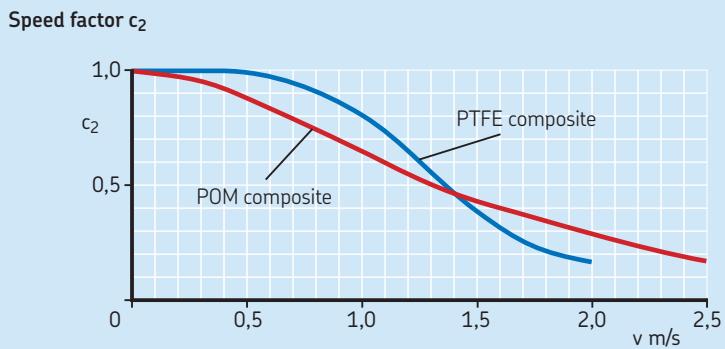

F = dynamic bearing load, kN

C = basic dynamic load rating, kN

K = specific load factor, N/mm²

= 80 for PTFE composite material

= 120 for POM composite material

Diagram 4

For flanged bushings, the specific load of the bushing and flange should be calculated separately. To calculate the specific load of the flange, replace C with C_a in the equation above. Values for C_a can be found in the product tables.

Determining sliding velocity

The sliding velocity for SKF composite bushings and thrust washers can be obtained from

$$v = 5,82 \times 10^{-7} d \beta f$$

where

v = sliding velocity, m/s

d = sliding diameter, mm

- bushings and flanged bushings: bore diameter d

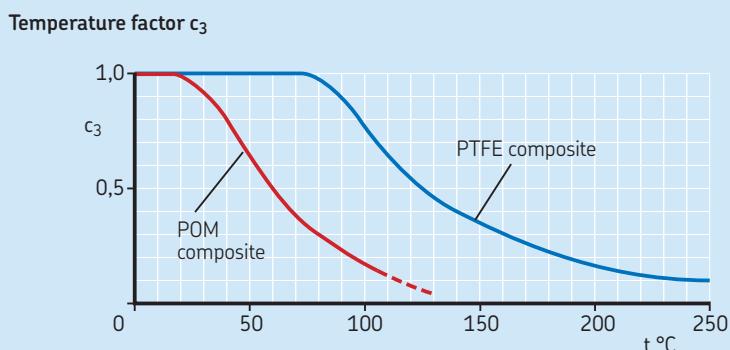

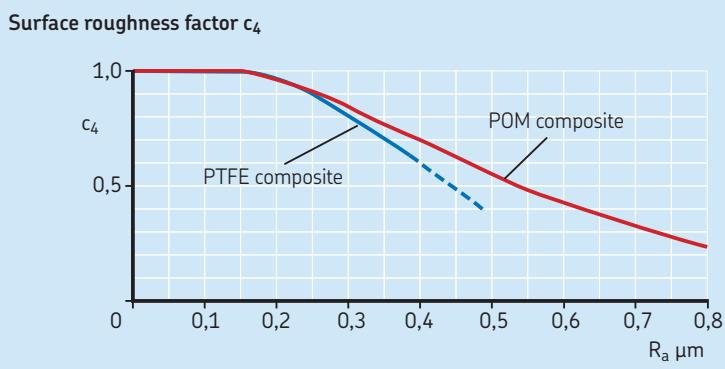

- flange of flanged bushings:
mean diameter = 0,5 ($d + D_1$)

- thrust washers:
mean diameter = 0,5 ($d + D$) or dimension J in the product table

f = frequency of oscillation, min⁻¹, or
rotational speed, r/min

β = half the angle of oscillation, degrees
(→ fig. 1)

A complete oscillation (from point 0 to point 4) = 4 β . For rotation, use $\beta = 90^\circ$.

Diagram 5**Diagram 6**

Calculating basic rating life

Many factors influence the life of a plain bearing, e.g. load, sliding velocity, operating temperature, surface roughness of the counter surface against which the composite sliding layer runs, etc. Any calculation is therefore only approximate.

The values obtained using the basic rating life equations are attained by the majority of bearings and are often exceeded. This has been confirmed by rig tests and field experience.

The basic rating life for SKF PTFE composite and POM composite plain bearings can be calculated from

$$G_h = c_1 c_2 c_3 c_4 c_5 \frac{K_M}{(pv)^n}$$

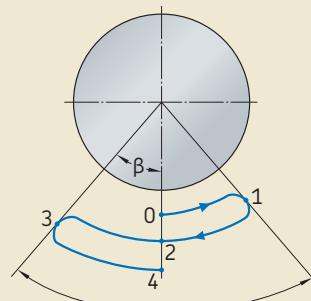

where

- G_h = basic rating life, operating hours
- c_1 = load factor (\rightarrow diagram 3)
- c_2 = speed factor (\rightarrow diagram 4)
- c_3 = temperature factor (\rightarrow diagram 5)
- c_4 = surface roughness factor
(\rightarrow diagram 6))
- c_5 = factor for the type of load
 - = 1 for stationary load (i.e. the loaded zone is always at the same position on the bearing circumference)
 - = 1,5 for rotating load (i.e. the loaded zone moves round the circumference of the bearing)
- K_M = factor depending on material and bearing type
 - = 480 for PTFE composite bushings
 - = 300 for PTFE composite thrust washers
 - = 1 900 for POM composite bushings and thrust washers
- p = specific bearing load, N/mm²
- v = sliding velocity, m/s
- n = an exponent
 - = 1 for PTFE composite bushings and thrust washers
 - = 1 for $pv \leq 1$ for POM composite bushings and thrust washers
 - = 3 for $pv > 1$ for POM composite bushings and thrust washers

If loads are very light and/or sliding velocities are very low and the value of the product pv

- for PTFE composite bearings is less than the limiting value of 0,025, then the limiting value $pv = 0,025$ should be used for the life calculations
- for POM composite bearings is less than the limiting value of 0,1 then the limiting value $pv = 0,1$, should be used for the life calculations.

Fig. 1

Angle of oscillation

φ = angle of oscillation = 2β
A complete oscillation = 4β
(from point 0 to point 4)

Calculation example

Two paired PTFE composite bushings are to be used in the linkage of a locking system for the door of a tramway car.

Design data:

- Pin diameter: $d = 20 \text{ mm}$
- Surface roughness of the pin: $R_a = 0,4 \mu\text{m}$

Operational data:

- Radial load at the linkage:
 - during closing $0,8 \text{ kN}$ per bushing
 - after locking the closed door the static load mounts to 15 kN per bushing
- Half angle of oscillation $\beta = 90^\circ$ ($\rightarrow \text{fig. 1}$)
- Frequency of oscillation: $f = 10 \text{ min}^{-1}$
- Operating temperature: $t = 30^\circ \text{C}$

Based on the design characteristics two PTFE composite bushings PCM 202325 E are chosen, having a basic dynamic load rating $C = 39 \text{ kN}$ each.

Check whether the bushings can be used under the given operating conditions and which basic rating life can be achieved.

As a first check that the bearing size is suitable ($\rightarrow \text{diagram 1 on page 10}$) the specific bearing load p based on the specific load factor $K = 80$ for PTFE composite is calculated using

$$p = K \frac{F}{C} = 80 \times \frac{0,8}{39} \approx 1,64 \text{ N/mm}^2$$

The sliding velocity is calculated using

$$v = 5,82 \times 10^{-7} d \beta f$$

$$= 5,82 \times 10^{-7} \times 20 \times 90 \times 10 = 0,01 \text{ m/s}$$

These values are within range I of the pv diagram for PTFE composite bearings ($\rightarrow \text{diagram 1 on page 10}$). Furthermore

- the load factor $c_1 = 1,3$ ($\rightarrow \text{diagram 3}$)
- the speed factor $c_2 = 1$ ($\rightarrow \text{diagram 4}$)
- the temperature factor $c_3 = 1$ ($\rightarrow \text{diagram 5}$)
- the surface roughness factor $c_4 = 0,6$ ($\rightarrow \text{diagram 6}$)
- the factor for the type of load $c_5 = 1,5$, as the load is rotating
- exponent $n = 1$, for PTFE composite material.

- pv value = 0,025, as the value of product $p \times v = 1,64 \times 0,1 = 0,0164$ is less than the limiting value of 0,025 for PTFE composite material ($\rightarrow \text{page 13}$).

Using the material and bearing type factor

$K_M = 480$ for PTFE composite bushings, the basic rating life for the chosen bushings can be calculated from

$$G_h = c_1 c_2 c_3 c_4 c_5 \frac{K_M}{(pv)^n}$$

$$G_h = 1,3 \times 1 \times 1 \times 0,6 \times 1,5 \times \frac{480}{(0,025)^1}$$

$$G_h \approx 22\,500 \text{ operating hours}$$

With a frequency $f = 10 \text{ min}^{-1}$, the working cycles amount to approximately 13,5 millions. The static load of 15 kN lies within the dynamic load rating of $C = 39 \text{ kN}$ and far below the static load rating of $C_0 = 120 \text{ kN}$. Thus, the chosen bushings meet the requirements.

Application of bearings

B

Material and surface finish of counterfaces

The factors that are most important to consider when selecting the material and surface finish of the counterface (the surface on which the bearing slides) are the loading conditions (load, angle of oscillation, type of movement etc.) and the environmental influences.

Where there is a risk of corrosion, the counterface should be sufficiently resistant. Corrosion scars in the counterface and the by-product of corrosion (particulate contamination) increase the surface roughness and are abrasive and will accelerate wear. In these cases, the use of stainless steel or a surface treatment such as hard chromium, nickel plating or electrolytic oxidation should be considered.

For PTFE composite and POM composite plain bearing arrangements, soft carbon steels with a ground surface are usually adequate for the counterface. The surface roughness R_a (to EN ISO 4287:1998 and EN ISO 1302:2002) should not exceed 0,4 μm for PTFE composite bearings and 0,8 μm for POM composite bearings. The corresponding R_z values are 3 and 6 μm , respectively. For more demanding applications the use of a hardened counterface is recommended. These should have a surface hardness of at least 50 HRC. Alternatively, hard chromium, nickel plating or some other form of surface treatment can be considered. In all cases R_a should not be greater than 0,3 μm ($R_z \leq 2 \mu\text{m}$). The better the surface finish, the better the running and wear properties (→ Surface roughness factor c_4 , **diagram 6, page 12**).

Shaft and housing tolerances

SKF recommends machining the seating in the housing bore to an H7 tolerance for metric PTFE composite and POM composite plain bushings (including flanged bushings), except for small bearings with a diameter up to 4 mm where H6 is recommended. If the shaft seating also meets the recommended tolerances, the clearance in the bearing arrangement will lie within the limits provided in **table 1 on page 16** for PTFE composite plain bushings and in **table 2 on page 17** for POM composite plain bushings, respectively.

The shaft and housing limits for inch bushings are provided in **table 3 on page 19** for PTFE composite plain bushings and in **table 4 on page 21** for POM composite plain bushings, together with the corresponding limits for the bushing bore diameter after mounting and the operating clearance.

The values quoted for operating clearance are valid at room temperature. If the operating temperature is higher than that, it is expected that the operating clearance of

- PTFE composite bushings will be reduced by 0,0016 mm
- POM composite bushings will be reduced by 0,005 mm

for every 20 °C temperature increase. The actual operating clearance can be increased or decreased within the recommended limits by matching shaft and housing bores having appropriate diameter values within the specified limits.

If in certain applications smooth running is required, or if the bearing is only lightly loaded, SKF recommends tolerancing the application so that maximum values for operating clearance are realized.

The recommended tolerances and guideline limits quoted in the tables are valid for steel and cast iron housings. Where light alloy housings are used, a greater degree of interference may be required because of the different thermal expansion characteristics of the housing and the bushing. There is otherwise a risk that the greater thermal expansion of the housing would no longer provide radial location for the bushing and that the operating clearance would be too large.

If it is not possible to adopt a greater interference fit, it might be possible to use an adhesive to retain the bushing. In special cases it may be necessary, by selecting a suitable tolerance for the shaft, to prevent an inadmissible increase in operating clearance.

Table 1

Metric PTFE composite bushings – shaft and housing tolerances, operating clearance

Bushing dimensions				Diameter limits		Housing bore		Bore diameter of mounted bushing		Operating clearance	
Bore diameter	Outside diameter			Shaft (f7 for d ≤ 75 mm) (h8 for d > 75 mm)		(H7)					
d	D	max	min	max	min	max	min	max	min	min	max
mm									μm		
3	4,5	0,750	0,730	3,000 (h6)	2,994 (h6)	4,508 (H6)	4,500 (H6)	3,048	3,000	0	54
4	5,5	0,750	0,730	4,000 (h6)	3,992 (h6)	5,508 (H6)	5,500 (H6)	4,048	4,000	0	56
5	7	1,005	0,980	4,990	4,978	7,015	7,000	5,055	4,990	0	77

Design of associated components

Straight bushings

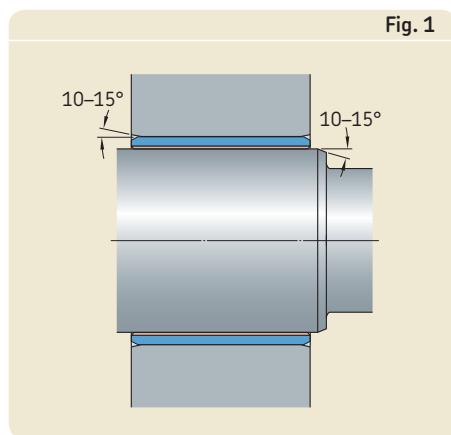

To prevent the sliding surface from becoming stepped, the sliding surface of the shaft, i.e. the counterface, should always be wider than the actual bushing width – particularly where axial displacement of the shaft relative to the housing may occur as a result of axial expansion.

To facilitate mounting, shaft ends and housing bores should have a lead-in chamfer with an angle of 10 to 15° (→ fig. 1). These chamfers will make it easier to press the bushings into the housing bore and to insert the shaft into the bushing bore, without the risk of damaging the sliding surface.

The housing shoulders intended to locate the bushing axially should have a diameter that is equal to or greater than $d + 0,8$ mm.

When PTFE composite bushings operate without a lubricant it is especially important to accurately align all bearing positions. If misalignment between the positions cannot be avoided, take steps during the design stage to prevent inadmissibly high edge stresses from occurring. For example, the housing bore seating can be relieved on both sides, or a wider bushing can be used so that it extends beyond the housing bore seating on both sides (→ fig. 2).

Lead-in chamfers for housing bores and shaft ends

In case of misalignment have to be compensated for and the operating conditions permit the use of POM composite, then the bushings of this material should be chosen. The covering layer of this material can be machined to a minimum degree after the bushing has been mounted in a housing bore.

provided in the housing, the thrust washer can be attached to the housing by two pins or screws (→ fig. 6) or by gluing. The heads of the pins or screws must be recessed to at least 0,3 mm below the sliding surface and the entire surface of the thrust washer must be supported.

B

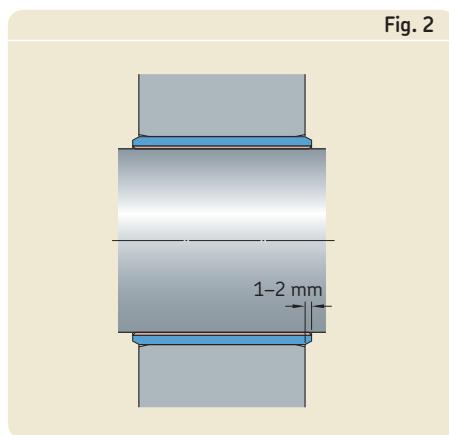

Flanged bushings and thrust washers

For shafts that need radial support and axial location, flanged bushings or a combination bushing-thrust washer (→ fig. 3) can be used depending on the magnitude of the axial load. Flanged bushings or thrust washers are advantageous even if axial loads are light and a surface is not adequate to accommodate the thrust, either because the material or its finish is unsuitable.

Note that the counterface should completely cover the sliding surface of the thrust washer and the flange of a flanged bushing (→ fig. 4). For bearing arrangements where flanged bushings are used, the transition from housing bore to abutment should be chamfered so that it does not contact the bushing where it meets the flange (→ fig. 5).

A thrust washer is generally located in a housing recess (→ fig. 3) and secured by a dowel pin or grub screw to prevent it from rotating. The appropriate dimensions for this type of location are provided in the product tables. If for some reason, a recess cannot be

Bushing extending beyond the bearing seating in the housing on both sides to prevent inadmissibly high edge stresses

Combination of a bushing and thrust washer

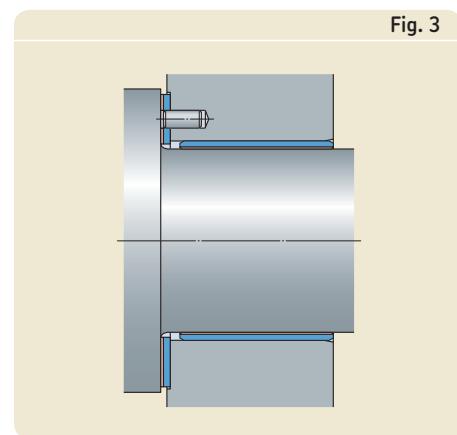

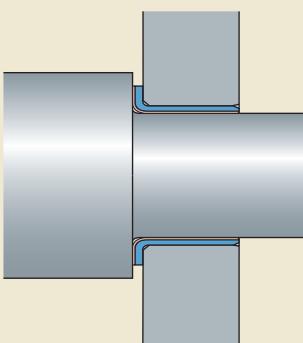

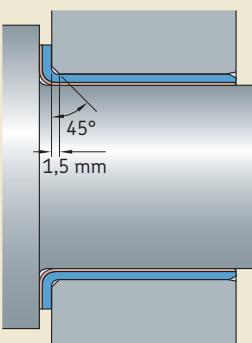

Fig. 4

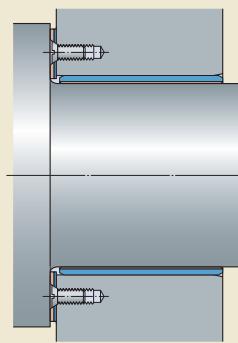

The mating surface should cover the entire surface of the flange

Fig. 5

The transition between housing bore and support surface must be sufficiently large

Fig. 6

Thrust washer secured by two screws

Seals

Seals can decisively influence the service life of composite plain bearings. When selecting seals consider, for example, the design, the available space and the justifiable expense.

Composite plain bearings, particularly the POM composite, are able to embed contaminant particles and are thus relatively insensitive to contamination. They generally require no special protection against normal airborne dirt. If, however, the bearing position is subjected to heavier contamination it should be sealed from the outside. Simple and efficient sealing can be obtained if adjacent components can also serve as seals (→ fig. 7).

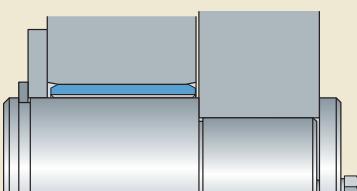

Radial shaft seals with a low cross section, e.g. seals in the G series, as used for needle roller bearings, can provide adequate protec-

tion for composite plain bearings in most cases (→ fig. 8). If the demands placed on the sealing arrangement are high, it may be necessary to resort to special seals of rubber, plastic or similar materials (→ fig. 9).

In highly contaminated environments, particularly where sand or clay is present, rubber or plastic seals tend to have a very short service life. Under these conditions, a good seal can be achieved by periodically relubricating the bushing.

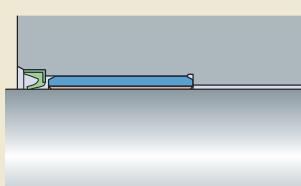

Adjacent components serve as seals

Fig. 7

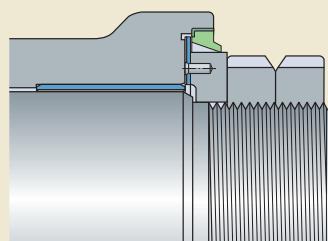

A shaft seal with low cross sectional height can be used

Fig. 8

Sealing with a wiper-scraper seal of nitrile rubber

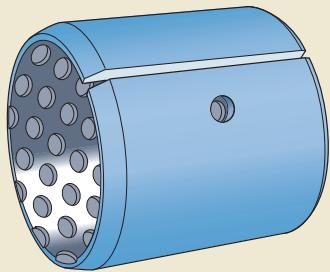

Fig. 9

Lubrication

B

Fig. 1

POM composite straight bushing with a lubrication hole

PTFE composite bearings

PTFE composite plain bearings have good dry sliding characteristics and do not require lubrication. However, the use of other lubricants not normally associated with bearings such as water, kerosene or paraffin, can be used.

A lubricant helps to dissipate heat from the bearing position as it forms a hydrodynamic lubricating film to reduce wear and extend bearing service life. However, relubrication is also very important.

If a bearing is greased during mounting to enhance sealing or to protect the counterface against corrosion, bearing service life will be extended, provided the bearing is relubricated periodically. If the bearing is not relubricated, the grease will form a paste-like mixture with the wear particles produced during run-in. This paste will significantly accelerate bearing wear.

POM composite bearings

POM composite plain bearings require an initial application of grease during mounting. Relubrication is not required but the presence or constant supply of a lubricating fluid or grease can extend bearing service life considerably.

For this reason POM composite bushings with a bore diameter ≥ 10 mm and a width ≥ 12 mm are available as standard with a lubrication hole (\rightarrow fig. 1). The hole dimensions and position are in accordance with ISO 3547-3:2006.

Age-resistant greases with a lithium thickener are preferred for operating temperatures up to 80 °C, while at higher temperatures, silicone greases should be used. Greases containing solid lubricants such as molybdenum disulphide are totally unsuitable.

Mounting

Skill and care in mounting are prerequisites for long bearing service life. In addition, cleanliness, and understanding the causes of premature bearing failure can help too.

Check that the counterface (shaft seating) and other components like the housing are clean, deburred and that they do not contain any abrasive particles. Check also the shaft for sharp edges, burrs or surface defects, which could damage the sliding surface of the bushings as they are mounted. Once all the components have been cleaned and checked, the bushing is ready to be installed.

To install smaller PTFE or POM bushings, with or without a flange, a mounting dolly should be used (→ fig. 1). To do this, place an O-ring on the dolly to keep the bushing in position. Then drive the bushing into place with a mechanical or hydraulic press or by

tapping the dolly lightly with a hammer. To facilitate the mounting of small bushings, apply a light coating of oil or grease to the housing bore. For larger bushings, SKF recommends using a mounting ring (→ fig. 2) because it aligns and centres the bushing while it is being pressed into place. When mounting larger bushings, use a solid lubricant paste, like the SKF anti-fretting agent LGAF 3E, on the seating to reduce the risk of fretting corrosion and also to reduce the force required for mounting.

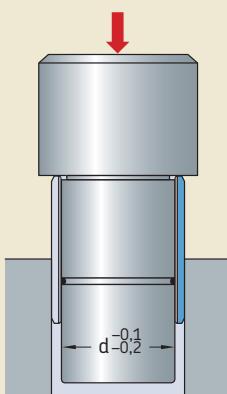

Composite straight bushings and flanged bushings which are to be heavily loaded in operation should be mounted so that the butt joint is at 90° to the loaded zone during operation (→ fig. 3), otherwise service life will be reduced. When mounting, thrust washers

should be positioned so that the steel backing abuts the housing wall.

If composite plain bearings are to be located in a housing using an adhesive, the adhesive should be suitable for the expected operating temperature and should have suitable expansion, ageing resistance, strength and curing properties. If no operational experience is available, SKF recommends contacting an adhesive manufacturer for advice. When applying an adhesive, care should be taken so that no adhesive reaches the sliding surface.

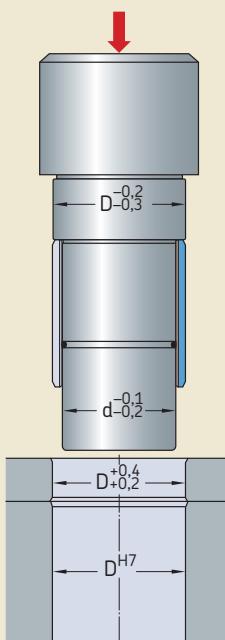

Mounting with a mandrel

Fig. 1

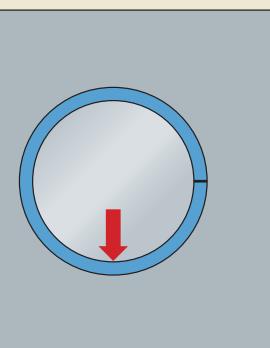

Mounting with a mandrel and mounting ring

Fig. 2

The main direction of the load must be at 90° to the plane of the butt joint

Fig. 3

Bearing data – general

Dimensions

The dimensions for metric straight bushings are in accordance, with few exceptions, with those specified in ISO 3547-1:2006.

The dimensions of inch bushings, flanged bushings and thrust washers have not been standardized.

Tolerances

Straight bushings: The tolerances for the outside diameter of metric straight bushings correspond to ISO 3547-1:2006. To check the values, use the procedure provided in ISO 3547-2:2006.

Flanged bushings: When mounted, the tolerances are a uniform $\pm 0,5$ mm for the flange diameter D_1 and $+0,05/-0,20$ mm for the width B_1 .

Thrust washers: The tolerances for the diameters are provided in the product table. The tolerances for the height are

- 0/-0,05 mm for PTFE composite washers
- 0/-0,10 mm for POM composite washers.

Strips: The tolerances for the height are

- 0/-0,05 mm for PTFE composite strips
- 0/-0,10 mm for POM composite strips.

Chamfer dimensions: The minimum values are provided in the product tables. Chamfer dimensions and tolerances for metric sizes are provided in **table 1**.

Operating clearances

The operating clearance of a bushing depends on its selected shaft and housing tolerances. Guideline values for metric bushings are provided in **tables 1** and **2**, on **pages 16 to 18**, and for inch bushings in **tables 3** and **4** on **pages 19 to 22**.

Excessive clearance may have a negative influence on the service life of PTFE composite bushings if they are not lubricated.

Permissible operating temperature range

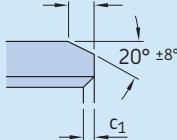

PTFE composite plain bearings can be used at temperatures between -200 and $+250$ °C.

The operating temperature range for POM composite bearings is -40 to $+110$ °C, although brief periods of operation at $+130$ °C are permissible.

The service life of SKF composite plain bearings will be reduced if operating temperatures exceed the limit values. This decrease in service life can be taken into account when calculating the basic rating life by the temperature factor c_3 (\rightarrow **diagram 5, page 12**).

Table 1

Chamfer dimensions and tolerances (metric sizes)

Wall thickness	$c_{1\min}$	$c_{1\max}$	c_2
mm	mm		
0.75	0.1	0.4	$0.5 +/- 0.3$
1	0.1	0.6	$0.6 +/- 0.4$
1.5	0.1	0.7	$0.6 +/- 0.4$
2	0.1	0.7	$1.2 +/- 0.4$
2.5	0.2	1.0	$1.8 +/- 0.6$

The prefix PCM identifies a metric and the prefix PCZ identifies an inch composite straight bushing. Supplementary letters, following these combinations identify other bearing types and have the following meaning:

- F: flanged bushing,
- S: strip,
- W: thrust washer.

In the case of metric bushings, flanged bushings and thrust washers, the combination of 6 to 9 figures identify the bore diameter (d), the outside diameter (D) and the width (B) or height (H). For example, a POM composite bushing with $d = 8$ mm, $D = 10$ mm and $B = 8$ mm is designated PCM 081008 M. Small bushings carrying the additional suffix VB055 are an exception to this: the outside diameter is 0,5 mm larger than indicated in the designation.

In the case of composite strips, the combination of figures identifies width, length and height.

The designations for inch bushings are similar but in this case the figures only identify the bore diameter (d) and the width (B) in $1/16$ ths of an inch. For example a PTFE composite bushing with bore diameter $d = 3/4 = 12/16$ inch and $B = 1/2 = 8/16$ inch is designated PCZ 1208 E.

The suffixes used to identify the material variant are listed below

- E: layer of PTFE with molybdenum disulfide additives
- M: layer of POM composite.

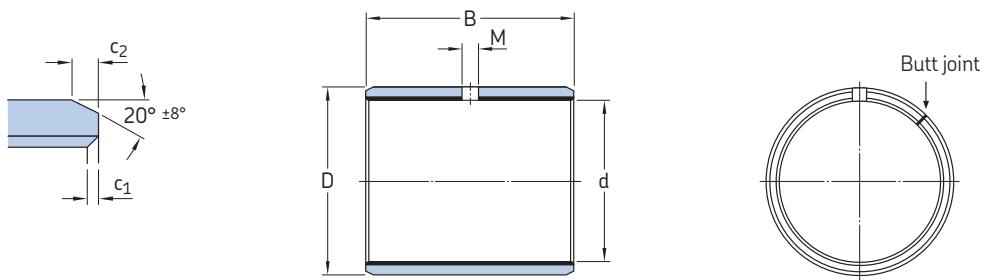

Product designations

The basic designation of SKF composite plain bearings consists of

- a prefix, a combination of three or four letters, which indicates the bearing type,
- a combination of 4 to 9 figures, identifying the size, and
- suffixes, identifying material and design variants.

Related SKF products

Maintenance-free filament wound bushings

Filament wound bushings are produced by winding a self-lubricating composite. The sliding layer consists of strands of high-strength polyester and reinforced PTFE (polytetrafluoroethylene) in an epoxy resin matrix. The shell or backing is made of wound high-strength tensioned glass fibre also in an epoxy resin matrix. The sliding and backing layers are firmly anchored to each other. Both layers are produced by winding endless strands in a crisscross pattern.

Modern filament winding technology has made it possible to combine the special mechanical properties of glass fibre with the excellent tribological properties of high-strength thermoplastic and PTFE fibres

embedded in epoxy resin to produce a new innovative bearing material. The defined position of the strands in the crisscross pattern and the intensive binding between the strands and the resin provide very high load carrying capacity and wear-resistance.

Maintenance-free plain bearings, series designation PWM, are only available as cylindrical bushings. They are intended for oscillating, rotational and linear movement, where there is risk of heavy edge loading and/or where chemical resistance and maintenance-free operation are required. They can be used at temperatures between -50 and +140 °C.

Assortment

The range of SKF maintenance-free PWM bushings currently comprises bushings with bore diameters ranging from 20 to 300 mm.

Further information

More information about PWM bushings can be found in the

- "SKF Interactive Engineering Catalogue" online at www.skf.com
- brochure "SKF bushings"
- brochure "Filament wound bushings, PWM series".

SKF spherical plain bearings

For arrangements where alignment movements have to be accommodated between two components in relative motion or where tilting movements or oscillations occur at relatively low sliding velocities, spherical plain bearings are an excellent solution. They have an inner ring with a spheroid convex outside surface and an outer ring with a correspondingly spheroid but concave inside surface. Wherever spherical plain bearings are needed, whether maintenance-free or not, SKF spherical plain bearings can do the job.

Spherical plain bearings with steel-on-steel sliding contact surfaces require maintenance. The high wear-resistance of the sliding surfaces makes these bearings especially suitable for arrangements where there are heavy loads in alternating directions, shock loads or heavy static loads.

SKF maintenance-free spherical plain bearings incorporate special sliding layers of advanced materials that have very low friction. They are used in applications where long bearing service life is required without maintenance, or where operating conditions like inadequate lubrication or the absence of any lubricant do not allow the use of steel-on-steel bearings. SKF maintenance-free bearings are produced with three different sliding contact surface combinations, depending on bearing size and series. These sliding contact surface combinations are

- steel/PTFE sintered bronze
- steel/PTFE fabric
- steel/PTFE FRP

Assortment

The comprehensive SKF assortment comprises radial, angular contact and thrust bearings and covers a shaft diameter range from 4 to 1.000 mm.

Further information

For detailed information about SKF spherical plain bearings please refer to the

- "SKF Interactive Engineering Catalogue" online at www.skf.com
- PUB BU/P1 6116/1 "SKF spherical plain bearings and rod ends"

SKF rod ends

Rod ends have been designed for use in construction and control rod linkages, for the end of piston rods or the base of pneumatic or hydraulic cylinders. In these applications, tensile and compressive loads must be transmitted at the same time that alignment movements have to be accommodated. A rod end is basically an eye-shaped head with integral shank (the housing) and a self-aligning bearing. Most SKF rod ends incorporate a standard spherical plain bearing that is held in the housing bore by staking both sides or by retaining rings. The wide range of SKF rod ends can accommodate a wide range of operating conditions.

SKF rod ends with steel-on-steel or steel-on-bronze sliding contact surfaces require maintenance. These rod ends generally require periodic relubrication.

The high wear-resistance of steel-on-steel rod ends makes them especially suitable for arrangements where loads alternate direction or where there are relatively heavy static loads. Under these operating conditions but where lubricant starvation may be encountered, steel-on-bronze rod ends are recommended.

SKF maintenance-free rod ends are produced with three different sliding contact surface combinations, depending on size and series. These sliding contact surface combinations are

- steel/PTFE sintered bronze
- steel/PTFE fabric
- steel/PTFE FRP

The sliding layers of modern materials that have very low friction are the same as those used for SKF maintenance-free spherical plain bearings.

Assortment

The SKF assortment comprises male or female rod ends with right or left-hand thread and also with welding shank. The latter are only available as steel-on-steel rod ends as standard. The assortment covers a pin diameter range between 5 and 200 mm.

Further information

For detailed information about SKF rod ends please refer to the

- "SKF Interactive Engineering Catalogue" online at www.skf.com
- PUB BU/P1 6116/1 "SKF spherical plain bearings and rod ends".

Application examples

The unique properties and excellent performance of composite plain bearings have led to their use in a variety of industrial, domestic and other applications. They are particularly suitable for conditions where both maintenance and lubrication are either not required or not possible. Examples of typical existing applications for these bearings are as follows.

Automotive

King pins, starter pinions, brake rod linkages, brake shafts, brake shoes, suspensions, window lifts, foot pedals, accelerator linkages, fans, propeller shafts, clutch release levers, steering rods, steering columns, swinging arms, shock absorbers, carburettor butterfly valves etc.

Rail vehicles, railway installations

Automatic doors, level crossing barriers, brakes, pantographs, controllers, load switches, relay boxes, signalling equipment, wagons, points etc.

Aerospace

Brakes, electronic equipment, undercarriages, engines, radar equipment, control devices etc.

Construction industry, conveying equipment

Lifts, excavator drives, excavator arms, excavator control equipment, concrete mixers, fork lift trucks, hydraulic rams, chain tensioning sprockets, crane drives, crane control equipment, crane jibs, mortar carriers, pallet lift trucks, pneumatic lifts, caterpillar graders, escalators, moving pavements, vibrating screens, slides, shuttering cleaning machines, low loader trailers, winches, conveyors of all kinds etc.

Office machines and equipment

Addressing machines, data processing equipment, tape recorders, swiveling chairs, franking machines, copiers, blueprint copiers, drawing tables, drawing machines etc.

Domestic appliances, hospital equipment

Dental equipment, dishwashers, ironing machines, air conditioning equipment, hospital beds, refrigerators, sewing machines, operating tables, X-ray equipment, vacuum cleaners, washing machines etc.

Agricultural machines and food-processing machinery

Bottling machines, bakery equipment, timber saws, filtering centrifuges, abattoir and meat processing equipment, hay tedders, potato harvesters, wine-making equipment, loaders, unloaders, combine harvesters, mills, planting machines, root crop harvesters, balers, tractors, tractor seats, automatic packaging equipment, weighing equipment etc.

General engineering

Chamfering machines, bending machines, machines for sheet metal working, briquetting machines, forge machinery, woodworking machines, plastic moulding machines, presses, automatic welding equipment, machine tools, crushing plants etc.

Papermaking and textile machines

Cutting machines, printing machines, doubling machines, folding machines, yarn and wool machines, vulcanizing machines, carders, button machines, papermaking and paper-treating machinery, sorting devices, spinning machines, stuffers, knitting machines, looms etc.

Pumps and valves

Axial and radial piston pumps, metering pumps, firefighting pumps, compressors, ball cocks, mixer valves, oil burners, pumps for chemicals, regulating valves, submersible pumps, vacuum pumps, spur gear pumps etc.

Electrical equipment

Starting levers for electric motors, contactors, control equipment, switch gear etc.

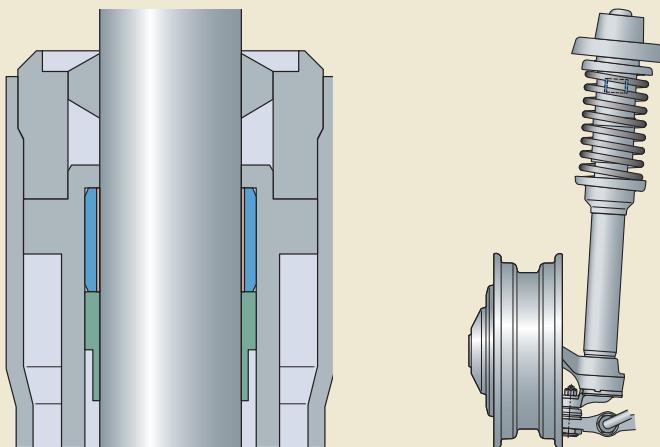

Automatic devices and tools

Charging and feeding devices, vending machines, pneumatic tools, hydraulic tools etc.

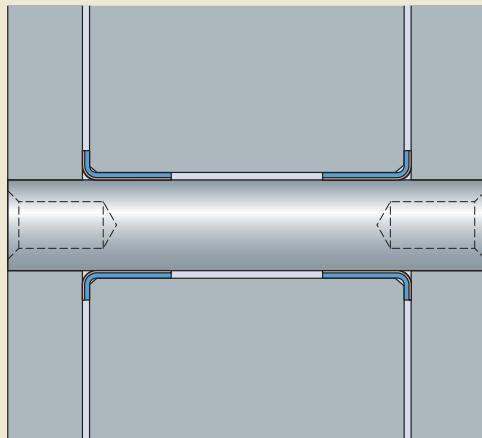

Other uses

Refuse disposal equipment and plant, brake magnets, heat treatment plant, blinds, awnings, smelting furnaces, continuously variable gears, drying plant, steel construction etc.

for the rotor on
an underwater pump
with PTFE composite
straight bushings*

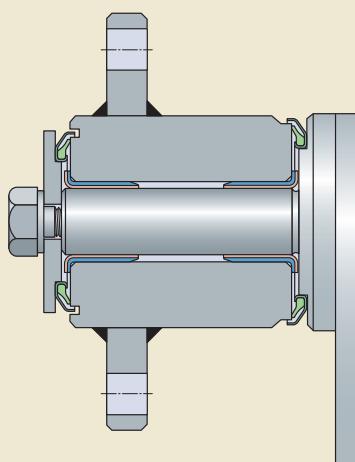

Coupling rod bearing arrangement for a printing press gear lever with PTFE composite straight bushings

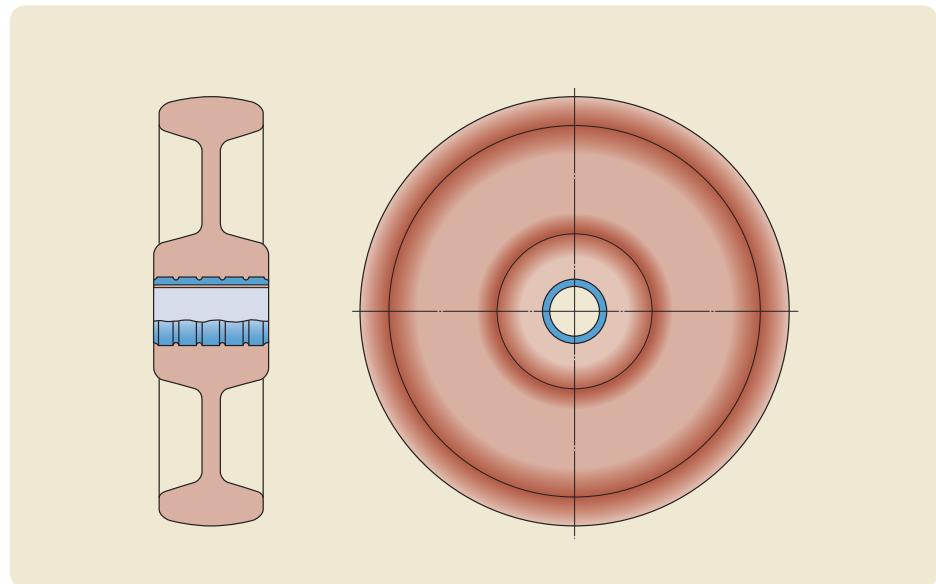

Bearing arrangement for a conveyor roller with a PTFE composite straight bushing

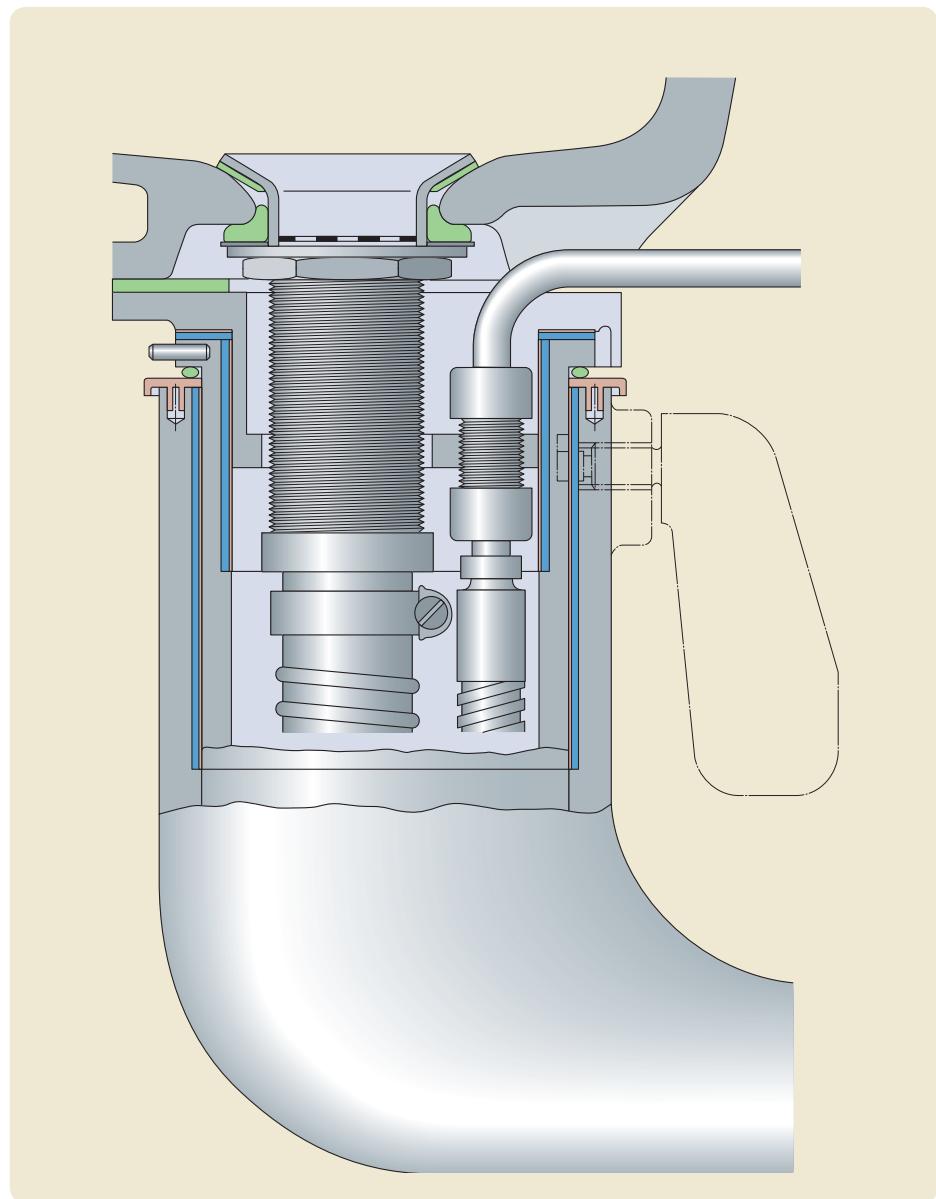

Bearing arrangement for the cutter on debarking equipment with flanged PTFE composite straight bushings

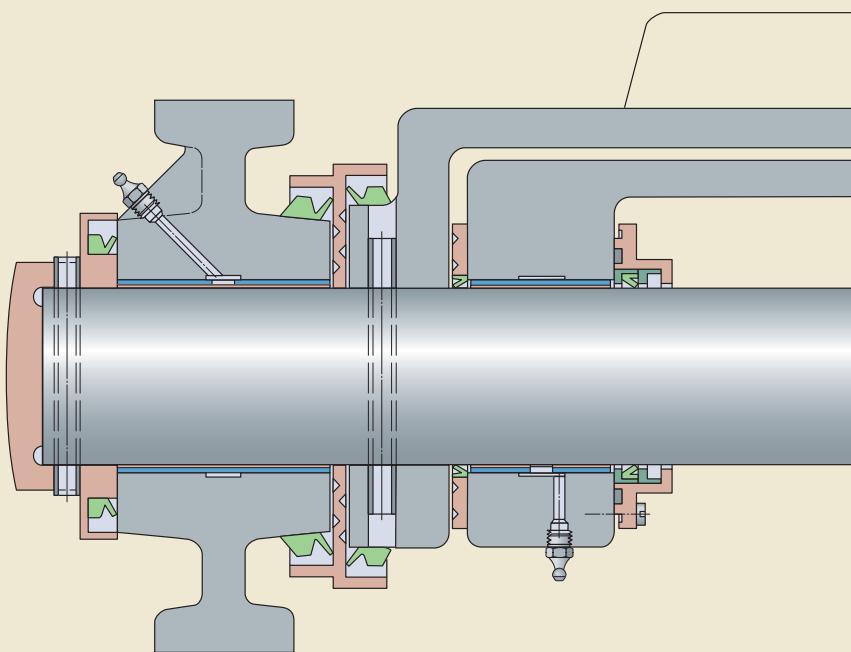

Bearing arrangement for the castors on an airline catering trolley with PTFE composite straight bushings

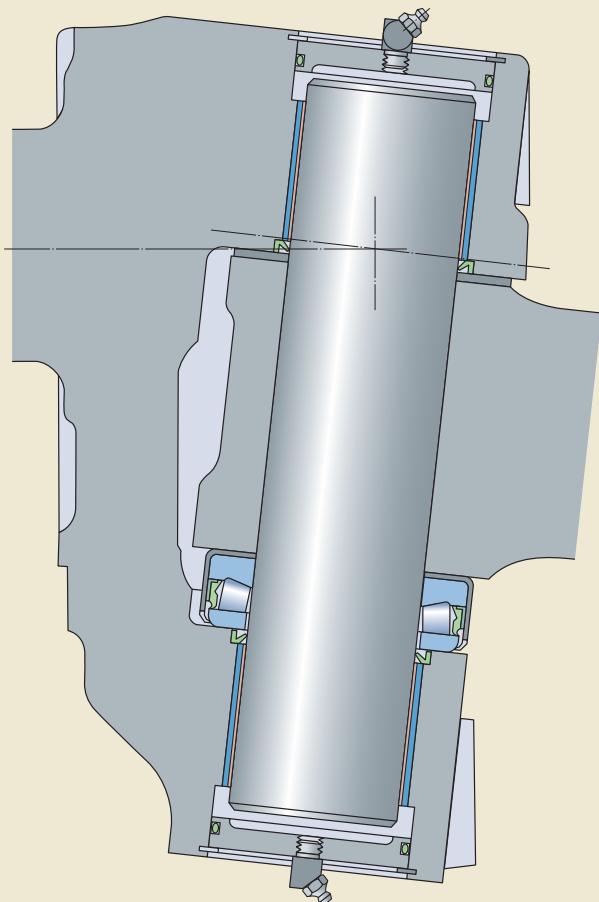

Swivelling device for a washbasin column with POM composite straight bushings

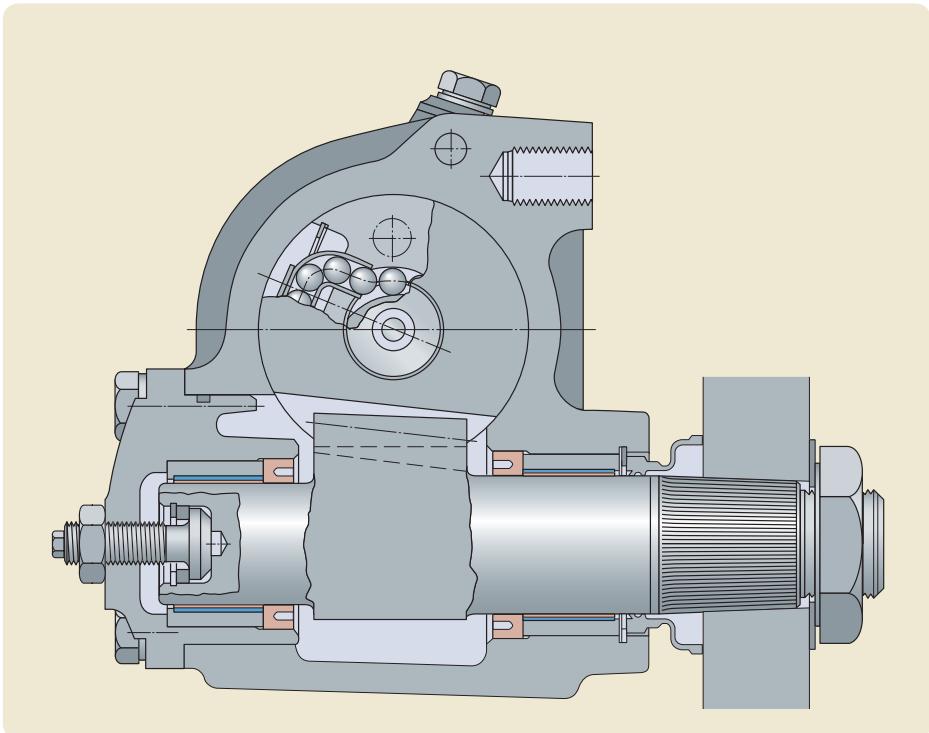

Bearing arrangement for the platform and side rollers of a platform conveyor with POM composite straight bushings

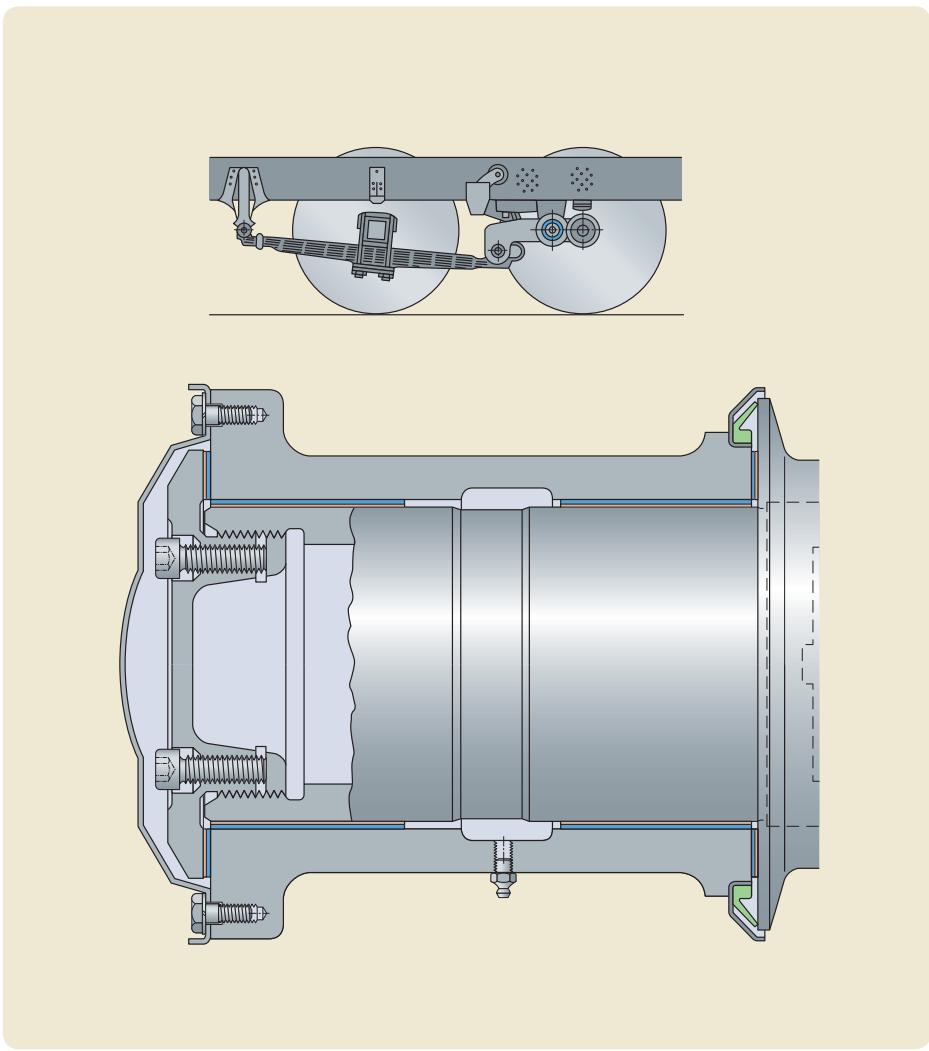

King pin bearing arrangement with POM composite straight bushings

Bearing arrangement for the linear guide of a truck servo steering unit with PTFE composite bushings.

Bearing arrangement for a lift-off axle with POM composite straight bushings and thrust washers

SKF – the knowledge engineering company

From the company that invented the self-aligning ball bearing more than 100 years ago, SKF has evolved into a knowledge engineering company that is able to draw on five technology platforms to create unique solutions for its customers. These platforms include bearings, bearing units and seals, of course, but extend to other areas including: lubricants and lubrication systems, critical for long bearing life in many applications; mechatronics that combine mechanical and electronics knowledge into systems for more effective linear motion and sensorized solutions; and a full range of services, from design and logistics support to condition monitoring and reliability systems.

Though the scope has broadened, SKF continues to maintain the world's leadership in the design, manufacture and marketing of rolling bearings, as well as complementary products such as radial seals. SKF also holds an increasingly important position in the market for linear motion products, high-precision aerospace bearings, machine tool spindles and plant maintenance services.

The SKF Group is globally certified to ISO 14001, the international standard for environmental management, as well as OHSAS 18001, the health and safety management standard. Individual divisions have been approved for quality certification in accordance with ISO 9001 and other customer specific requirements.

With over 120 manufacturing sites worldwide and sales companies in 70 countries, SKF is a truly international corporation. In addition, our distributors and dealers in some 15 000 locations around the world, an e-business marketplace and a global distribution system put SKF close to customers for the supply of both products and services. In essence, SKF solutions are available wherever and whenever customers need them. Overall, the SKF brand and the corporation are stronger than ever. As the knowledge engineering company, we stand ready to serve you with world-class product competencies, intellectual resources, and the vision to help you succeed.

Evolving by-wire technology

SKF has a unique expertise in the fast-growing by-wire technology, from fly-by-wire, to drive-by-wire, to work-by-wire. SKF pioneered practical fly-by-wire technology and is a close working partner with all aerospace industry leaders. As an example, virtually all aircraft of the Airbus design use SKF by-wire systems for cockpit flight control.

SKF is also a leader in automotive by-wire technology, and has partnered with automotive engineers to develop two concept cars, which employ SKF mechatronics for steering and braking. Further by-wire development has led SKF to produce an all-electric forklift truck, which uses mechatronics rather than hydraulics for all controls.

Harnessing wind power

The growing industry of wind-generated electric power provides a source of clean, green electricity. SKF is working closely with global industry leaders to develop efficient and trouble-free turbines, providing a wide range of large, highly specialized bearings and condition monitoring systems to extend equipment life of wind farms located in even the most remote and inhospitable environments.

Working in extreme environments

In frigid winters, especially in northern countries, extreme sub-zero temperatures can cause bearings in railway axleboxes to seize due to lubrication starvation. SKF created a new family of synthetic lubricants formulated to retain their lubrication viscosity even at these extreme temperatures. SKF knowledge enables manufacturers and end user customers to overcome the performance issues resulting from extreme temperatures, whether hot or cold. For example, SKF products are at work in diverse environments such as baking ovens and instant freezing in food processing plants.

Developing a cleaner cleaner

The electric motor and its bearings are the heart of many household appliances. SKF works closely with appliance manufacturers to improve their products' performance, cut costs, reduce weight, and reduce energy consumption. A recent example of this cooperation is a new generation of vacuum cleaners with substantially more suction. SKF knowledge in the area of small bearing technology is also applied to manufacturers of power tools and office equipment.

Maintaining a 350 km/h R&D lab

In addition to SKF's renowned research and development facilities in Europe and the United States, Formula One car racing provides a unique environment for SKF to push the limits of bearing technology. For over 60 years, SKF products, engineering and knowledge have helped make Scuderia Ferrari a formidable force in F1 racing. (The average racing Ferrari utilizes around 150 SKF components.) Lessons learned here are applied to the products we provide to automakers and the aftermarket worldwide.

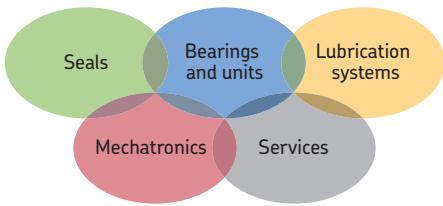

Delivering Asset Efficiency Optimization

Through SKF Reliability Systems, SKF provides a comprehensive range of asset efficiency products and services, from condition monitoring hardware and software to maintenance strategies, engineering assistance and machine reliability programmes. To optimize efficiency and boost productivity, some industrial facilities opt for an Integrated Maintenance Solution, in which SKF delivers all services under one fixed-fee, performance-based contract.

Planning for sustainable growth

By their very nature, bearings make a positive contribution to the natural environment, enabling machinery to operate more efficiently, consume less power, and require less lubrication. By raising the performance bar for our own products, SKF is enabling a new generation of high-efficiency products and equipment. With an eye to the future and the world we will leave to our children, the SKF Group policy on environment, health and safety, as well as the manufacturing techniques, are planned and implemented to help protect and preserve the earth's limited natural resources. We remain committed to sustainable, environmentally responsible growth.

The Power of Knowledge Engineering

Drawing on five areas of competence and application-specific expertise amassed over more than 100 years, SKF brings innovative solutions to OEMs and production facilities in every major industry worldwide. These five competence areas include bearings and units, seals, lubrication systems, mechatronics (combining mechanics and electronics into intelligent systems), and a wide range of services, from 3-D computer modelling to advanced condition monitoring and reliability and asset management systems. A global presence provides SKF customers uniform quality standards and worldwide product availability.
